

# Unit 3. Sensitivity Analysis

Jordi Villà i Freixa

Universitat de Vic - Universitat Central de Catalunya  
Study Abroad. Operations Research

*jordi.villa@uvic.cat*

9/05, 2023

This course is strongly based on the monography on Operations Research by Carter, Price and Rabadi [1], and in material obtained from different sources (quoted when needed through the slides).

# Learning outcomes

- Understanding the concept of postoptimality analysis
- Understanding and solving LP problems requiring sensitivity analysis
- Understanding the matrix representation of the Simplex solution

# The concept

- After an optimal solution is found, the analyst needs to review the problem parameters and the solution.
- This process is called **postoptimality analysis**:
  - confirming or updating problem parameters (cost and availabilities of activities and resources)
  - if changes need to be introduced in the original parameters, assessing their impact on the optimality of the solution.
- If changes are small re-optimization may not be needed.
- **Sensitivity analysis** is the study of the effect that types, ranges, and magnitude of changes in problem parameters have in the value of the objective function, *without the need to solving again the new linear problem*.

# Two types of parameter modifications

In a LP problem, I can have two situations

$$\begin{array}{ll} \max & \mathbf{c}^t \mathbf{x} \\ \text{subject to} & A\mathbf{x} \leq \mathbf{b}, \forall x_i \geq 0 \end{array}$$

I may have interest in knowing what happens with modifications in the parameters  $c$  or modifications in the parameters  $b$ .

# Case 1: sensitivity with respect to $c$

## Exercise 1

A farmer wants to minimize the cost of the food given of two different types of nutrients  $A$  and  $B$ , provided that she needs a minimum nutrition to be achieved.

	A	B	price
Feed 1	10	3	16
Feed 2	4	5	14
requirements	124	60	

Find how resilient is she to the changes in the price?

## Case 2: sensitivity with respect to $b$

In such cases we will explore the coefficients of the objective function in the dual problem, instead.

### Exercise 2

Given the LP problem

$$\begin{array}{ll}\text{maximize} & z = 16x_1 + 14x_2 \\ \text{subject to} & 10x_1 + 4x_2 \geq 124 \\ & 3x_1 + 5x_2 \geq 60 \\ & x_1, x_2 \geq 0\end{array}$$

Explore the sensitivity of the minimum value of  $z$  with respect to the parameters in the RHS of the constraints.

# Shadow price is the solution of the dual problem

Solving the dual problem gives a lot of insight into the actual situation.

## Exercise 3

In a company that manufactures two types of cans,  $A$  and  $B$ , the owners want to maximize the production, which dependence on a restricted amount of aluminum, the time the machines can devote to the work and the manpower is given the following table:

	A	B	limit
Aluminium	50	30	2000
Machine time	6	5	300
Labor	3	5	200
price	124	60	

Given an optimal solution of the problem, how the objective function will depend on variations in the different constraints?

# Some tools that help interpreting the calculations

Find *here* a code with the solution using ORtools.  
The Sensitivity analysis tool in Excel is nicely explained *here*.
